I'm running out of energy on what appeared to be a fairly straightforward project at first. This project is to move an ASP application from Win2K to a windows xp system. Technology churn apparently is making this endeavor quite a hassle.

Anyway...my latest problem has to do with the blunt but cryptic error

"the specified module could not be found".

What module?

I have found a link which says that if I identify the module, I can use this command:

```
regsvr32 %systemroot%\System32\xxxx.dll
```

My question is, how do I identify said dll? I tried looking in the IIS log, but didn't see anything I could be sure of.

Thanks in advance.

iis

I'm also having this problem. It's the most frustrating error message in the world. Surely there must be a log of some kind somewhere? – [izb](#) Jan 6, 2011 at 10:44

The "specified module not found" error could be because you don't have iissuba.dll in your C:\Windows\ folder. IISsuba is the "subauthentication" module that controls IUSR\_machinename's password. You can extract iissuba.dll from the CD or folder that you installed IIS from.

Would your site happen to be using CDONTS to send e-mails? CDONTS isn't installed by default on Windows XP - XP has CDO instead.
